

Fortify on Demand Security Review

Tenant: US Department of the Air Force
(USAF) - Offutt AFB

Application: MET

Release: met-10.0.0

Latest Analysis: 2021/05/17 06:27:33 PM

Latest
Assessment Type: Static+

Executive Summary

Tenant: US Department of the Air Force (USAF)
 - Offutt AFB

Application: MET

Release: met-10.0.0

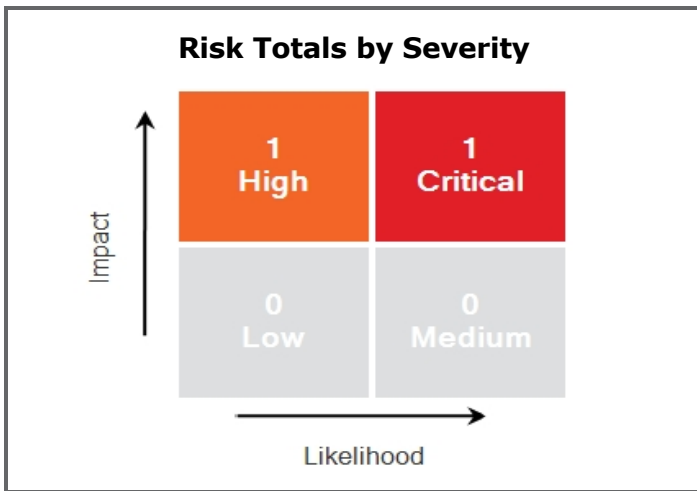

Business Criticality: High

SDLC Status: Production

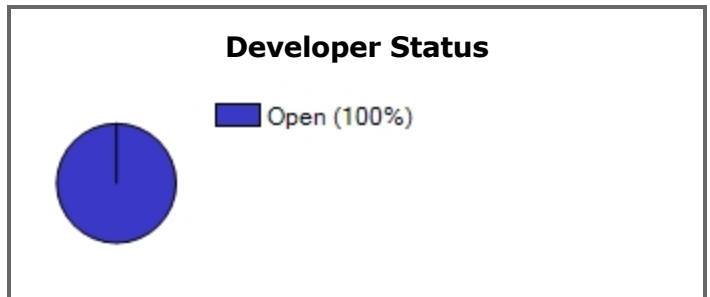

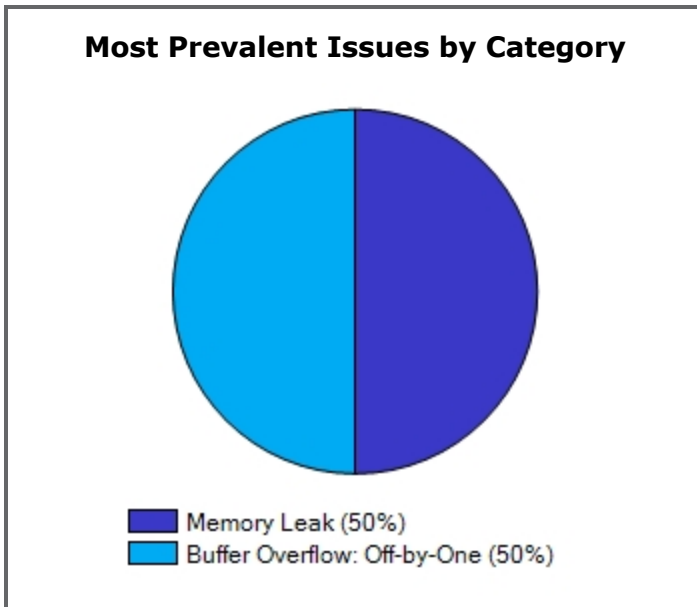

Static Analysis Date: 2021/05/17

Dynamic Analysis ---
 Date:

Fortify on Demand Security Rating  2 issues Status: Failed	
Static: 	Dynamic: 
Open Source: 	Monitoring: 

New	Existing	Reopened
2	0	0

Issue Breakdown

Issues are divided based on their impact (potential damage) and likelihood (probability of identification and exploit).

High impact / high likelihood issues represent the highest priority and present the greatest threat.

Low impact / low likelihood issues are the lowest priority and present the smallest threat.

See Appendix for more information.

Rating	Category	Test Type	
Critical	Buffer Overflow: Off-by-One	Static	1
High	Memory Leak	Static	1

Issue Breakdown by OWASP Top 10 2017 PCI Sections 6.3, 6.5 & 6.6

The OWASP Top Ten represents a broad consensus about what the most critical web application security flaws are. Project members include a variety of security experts from around the world who have shared their expertise to produce this list.

The PCI compliance standards, particularly sections 6.3, 6.5, and 6.6, reference the OWASP Top Ten vulnerability categories as the core categories that must be tested for and remediated.

OWASP Category	Severity			
	Critical	High	Medium	Low
A1 - Injection	1			
A2 - Broken Authentication				
A3 - Sensitive Data Exposure				
A4 - XML External Entities (XXE)				
A5 - Broken Access Control				
A6 - Security Misconfiguration				
A7 - Cross-Site Scripting (XSS)				
A8 - Insecure Deserialization				
A9 - Using Components with Known ...

Issue Detail

Below is an enumeration of all issues found in the project. The issues are organized by priority and category and then broken down by the package, namespace, or location in which they occur.

The priority of an issue can be Critical, High, Medium, or Low.

Issues from static analysis reported on at same line number with the same category originate from different taint sources.

6.1.1 Buffer Overflow: Off-by-One

Critical

CWE-787, CWE-131, CWE-129, CWE-805, CWE-193

OWASP Top 10: A1

PCI 3.2: 6.5.2 Buffer Overflows

Summary

The function `add_filter()` in `renderinfo.cc` writes one location past the bounds of `Filter` on line **169**, which could corrupt data, cause the program to crash, or lead to the execution of malicious code. The program writes just past the bounds of allocated memory, which could corrupt data, crash the program, or lead to the execution of malicious code.

Explanation

Buffer overflow is probably the best known form of software security vulnerability. Most software developers know what a buffer overflow vulnerability is, but buffer overflow attacks against both legacy and newly-developed applications are still quite common. Part of the problem is due to the wide variety of ways buffer overflows can occur, and part is due to the error-prone techniques often used to prevent them.

In a classic buffer overflow exploit, the attacker sends data to a program, which it stores in an undersized stack buffer. The result is that information on the call stack is overwritten, including the function's return pointer. The data sets the value of the return pointer so that when the function returns, it transfers control to malicious code contained in the attacker's data.

Although this type of off-by-one error is still common on some platforms and in some development communities, there are a variety of other types of buffer overflow, including stack and heap buffer overflows among others. There are a number of excellent books that provide detailed information on how buffer overflow attacks work, including Building Secure Software [1], Writing Secure Code [2], and The Shellcoder's Handbook [3].

At the code level, buffer overflow vulnerabilities usually involve the violation of a programmer's assumptions. Many memory manipulation functions in C and C++ do not perform bounds checking and can easily exceed the allocated bounds of the buffers they operate upon. Even bounded functions, such as `strncpy()`, can cause vulnerabilities when used incorrectly. The combination of memory manipulation and mistaken assumptions about the size or makeup of a piece of data is the root cause of most buffer overflows.

Example: The following code contains an off-by-one buffer overflow, which occurs when `recv` returns the maximum allowed `sizeof(buf)` bytes read. In this case, the subsequent dereference of `buf[nbytes]` will write the null byte outside the bounds of allocated memory.

```
void receive(int socket) {
char buf[MAX];
int nbytes = recv(socket, buf, sizeof(buf), 0);
buf[nbytes] = '\\0';
...
}
```

Execution

1. On Windows, less secure functions like `memcpy()` can be replaced with their more secure versions, such as `memcpy_s()`. However, this still needs to be done with caution. Because parameter validation provided by the `_s` family of functions varies, relying on it can lead to unexpected behavior. Furthermore, incorrectly specifying the size of the destination buffer can still result in buffer overflows.

Recommendation

Although the careful use of bounded functions can greatly reduce the risk of buffer overflow, this migration cannot be done blindly and does not go far enough on its own to ensure security. Whenever you manipulate memory, especially strings, remember that buffer overflow vulnerabilities typically occur in code that:

- Relies on external data to control its behavior.
- Depends upon properties of the data that are enforced outside of the immediate scope of the code.
- Is so complex that a programmer cannot accurately predict its behavior.

Additionally, consider the following principles:

- Never trust an external source to provide correct control information to a memory operation.
- Never trust that properties about the data your program is manipulating will be maintained throughout the program. Sanity check data before you operate on it.
- Limit the complexity of memory manipulation and bounds-checking code. Keep it simple and clearly document the checks you perform, the assumptions that you test, and what the expected behavior of the program is in the case that input validation fails.
- When input data is too large, be leery of truncating the data and continuing to process it. Truncation can change the meaning of the input.
- Do not rely on tools, such as StackGuard, or non-executable stacks to prevent buffer overflow vulnerabilities. These approaches do not address heap buffer overflows and the more subtle stack overflows that can change the contents of variables that control the program. Additionally, many of these approaches are easily defeated, and even when they are working properly, they address the symptom of the problem and not its cause.

6.2.1 Memory Leak

CWE-401

OWASP Top 10:

PCI 3.2: 6.5.6 High Risk Vulnerabilities

Summary

The function **open()** in **nccf_file.cc** allocates memory on line **346** and fails to free it. Memory is allocated but never freed.

Explanation

Memory leaks have two common and sometimes overlapping causes:

- Error conditions and other exceptional circumstances.

- Confusion over which part of the program is responsible for freeing the memory.

In this case the memory allocated in **nccf_file.cc** at line **346** is not always freed or returned by the function.

Most memory leaks result in general software reliability problems, but if an attacker can intentionally trigger a memory leak, the attacker may be able to launch a denial of service attack (by crashing the program) or take advantage of other unexpected program behavior resulting from a low memory condition [1].

Example 1: The following C function leaks a block of allocated memory if the call to `read()` fails to return the expected number of bytes:

```
char* getBlock(int fd) {
    char* buf = (char*) malloc(BLOCK_SIZE);
    if (!buf) {
        return NULL;
    }
    if (read(fd, buf, BLOCK_SIZE) != BLOCK_SIZE) {
        return NULL;
    }
    return buf;
}
```

Execution

1. Managed pointer objects, such as C++ `auto_ptr` and Boost smart pointers, are used to ensure that referenced memory allocations are freed. However, memory leaks can still occur when `auto_ptr`s or certain types of Boost smart pointers are used to reference arrays, Boost array pointers reference individual objects, and the `auto_ptr` release method is used.

Recommendation

Because memory leaks can be difficult to track down, you should establish a set of memory management patterns and idioms for your software. Do not tolerate deviations from your conventions.

One good pattern for addressing the error handling mistake in the example is to use forward-reaching `goto` statements so that the function has a single well-defined region for handling errors, as follows:

```

char* getBlock(int fd) {
char* buf = (char*) malloc(BLOCK_SIZE);
if (!buf) {
goto ERR;
}
if (read(fd, buf, BLOCK_SIZE) != BLOCK_SIZE) {
goto ERR;
}
return buf;

ERR:
if (buf) {
free(buf);
}
return NULL;
}

```

Appendix - Descriptions of Key Terminology

Security Rating

The Fortify on Demand 5-star assessment rating provides information on the likelihood and impact of defects present within an application. A perfect rating within this system would be 5 complete stars indicating that no high impact vulnerabilities were uncovered.

Rating	
	Fortify on Demand awards one star to applications that have undergone a security review that identifies critical (high likelihood and high impact) issues.
	Fortify on Demand awards two stars to applications that have undergone a security review that identifies no critical (high likelihood and high impact) issues. Vulnerabilities that are trivial to exploit and have a high business or technical impact should never exist in business-critical software.
	Fortify on Demand awards three stars to applications that have undergone a security review that identifies no high (low likelihood and high impact) issues and meets the requirements needed to receive two stars. Vulnerabilities that have a high impact, even if they are non-trivial to exploit, should never exist in business critical software.
	Fortify on Demand awards four stars to applications that have undergone a security review that identifies no medium (high likelihood and low impact) issues and meets the requirements for three stars. Vulnerabilities that have a low impact, but are easy to exploit, should be considered carefully as they may pose a greater threat if an attacker exploits many of them as part of a concerted effort or leverages a low impact vulnerability as a stepping stone to mount a high-impact attack.
	Fortify on Demand awards five stars, the highest rating, to applications that have undergone a security review that identifies no issues.

Likelihood and Impact

Likelihood

Likelihood is the probability that a vulnerability will be accurately identified and successfully exploited.

Impact

Impact is the potential damage an attacker could do to assets by successfully exploiting a vulnerability. This damage can be in the form of, but not limited to, financial loss, compliance violation, loss of brand reputation, and negative publicity.

Fortify on Demand Priority Order

Critical

Critical-priority issues have high impact and high likelihood. Critical-priority issues are easy to detect and exploit and result in large asset damage. These issues represent the highest security risk to the application. As such, they should be remediated immediately.

SQL Injection is an example of a critical issue.

High

High-priority issues have high impact and low likelihood. High-priority issues are often difficult to detect and exploit, but can result in large asset damage. These issues represent a high security risk to the application. High priority issues should be remediated in the next scheduled patch release.

Password Management: Hardcoded Password is an example of a high issue.

Medium

Medium-priority issues have low impact and high likelihood. Medium-priority issues are easy to detect and exploit, but typically result in small asset damage. These issues represent a moderate security risk to the application. Medium-priority issues should be remediated in the next scheduled product.

Path Manipulation is an example of a medium issue.

Low

Low-priority issues have low impact and low likelihood. Low-priority issues can be difficult to detect and exploit and typically result in small asset damage. These issues represent a minor security risk to the application. Low priority issues should be remediated as time allows.

Dead Code is an example of a low issue.

Issue Status

New

New issues are ones that have been identified for the first time in the most recent analysis of the application.

Existing

Existing issues are issues that have been found in a previous analysis of the application and are still present in the latest analysis.

Reopened

Reopened issues have been discovered in a previous analysis of the application but were not present in subsequent analyses. These issues are now present again in the most recent analysis of the application.
